

The solar system consists of the Sun and everything that orbits it, including eight planets, dwarf planets like Pluto, dozens of moons, and countless asteroids and comets. Mercury is the closest planet to the Sun, while Neptune is the farthest of the eight major planets. Earth is the only known planet to support life, thanks to its atmosphere, liquid water, and moderate distance from the Sun. Jupiter, the largest planet, has a mass greater than all other planets combined. Saturn is famous for its extensive ring system made mostly of ice particles.
